each forecast

**Should we be doing the
same for wildfire?**

The spectrum of fire models

empirical models
(e.g. Rothermel)

Fast, simplified, operationally used

“physics-based” models
(e.g. FIRETEC)

Detailed, computationally expensive, used in research

HIGRAD/FIRETEC: coupled fire-atmosphere modeling

HIGRAD/FIRETEC:

- High GRADient hydrodynamic model of atmospheric flow
- combustion and heat transfer model
- Discrete fuel beds at meter resolution

HIGRAD/FIRETEC: coupled fire-atmosphere modeling

- Research tool that can be used for simplified simulations of certain aspects of fire behavior, or portions of real wildfires

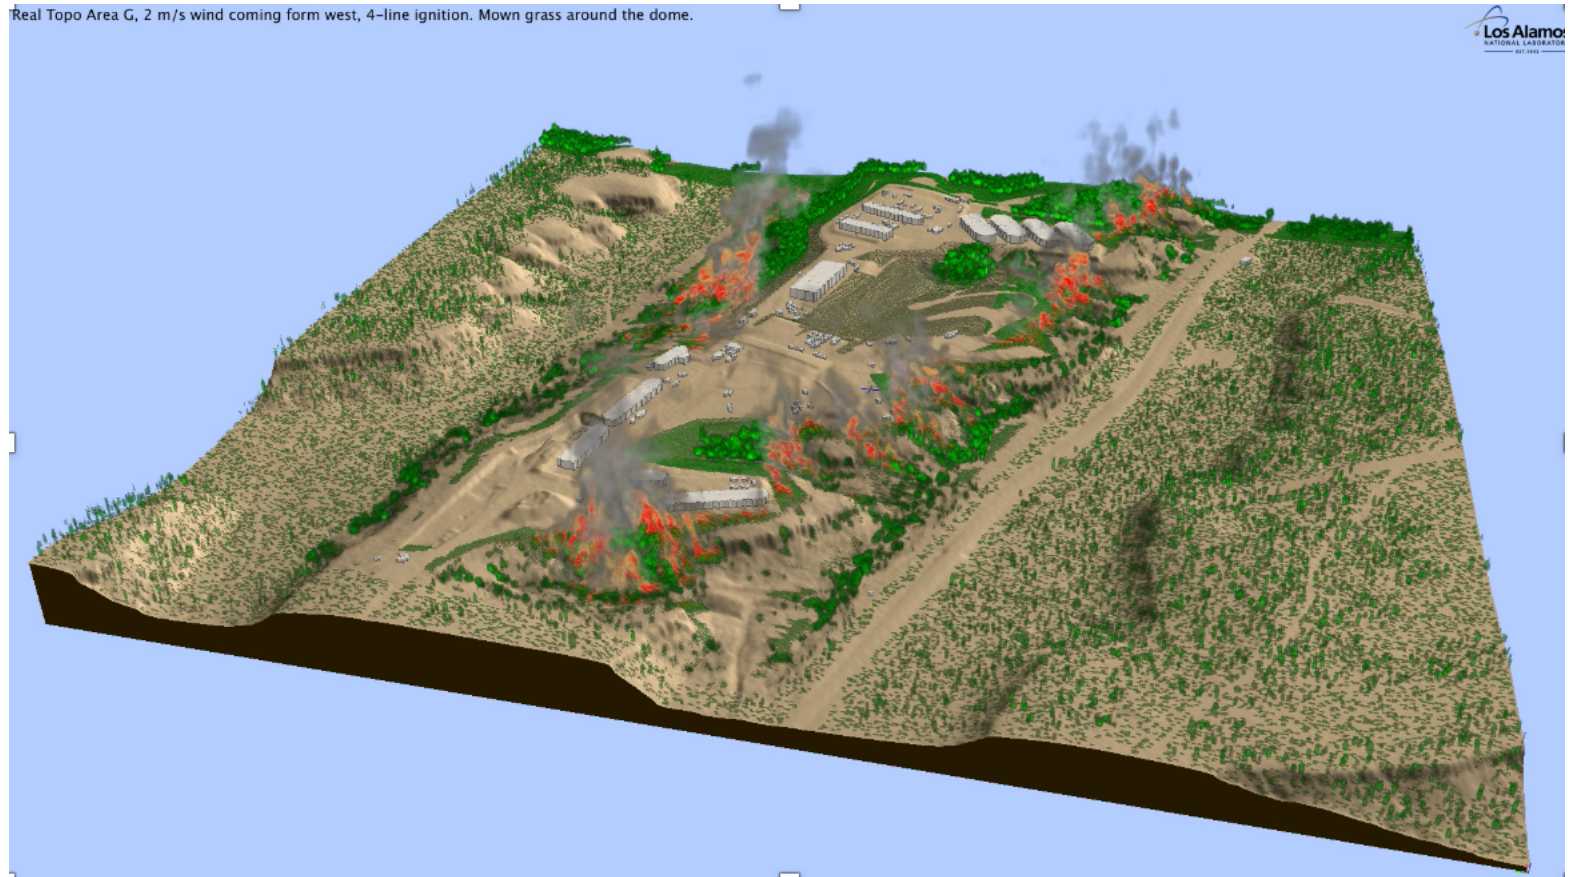

Movie removed for RASSTI

HIGRAD/FIRETEC: coupled fire-atmosphere modeling

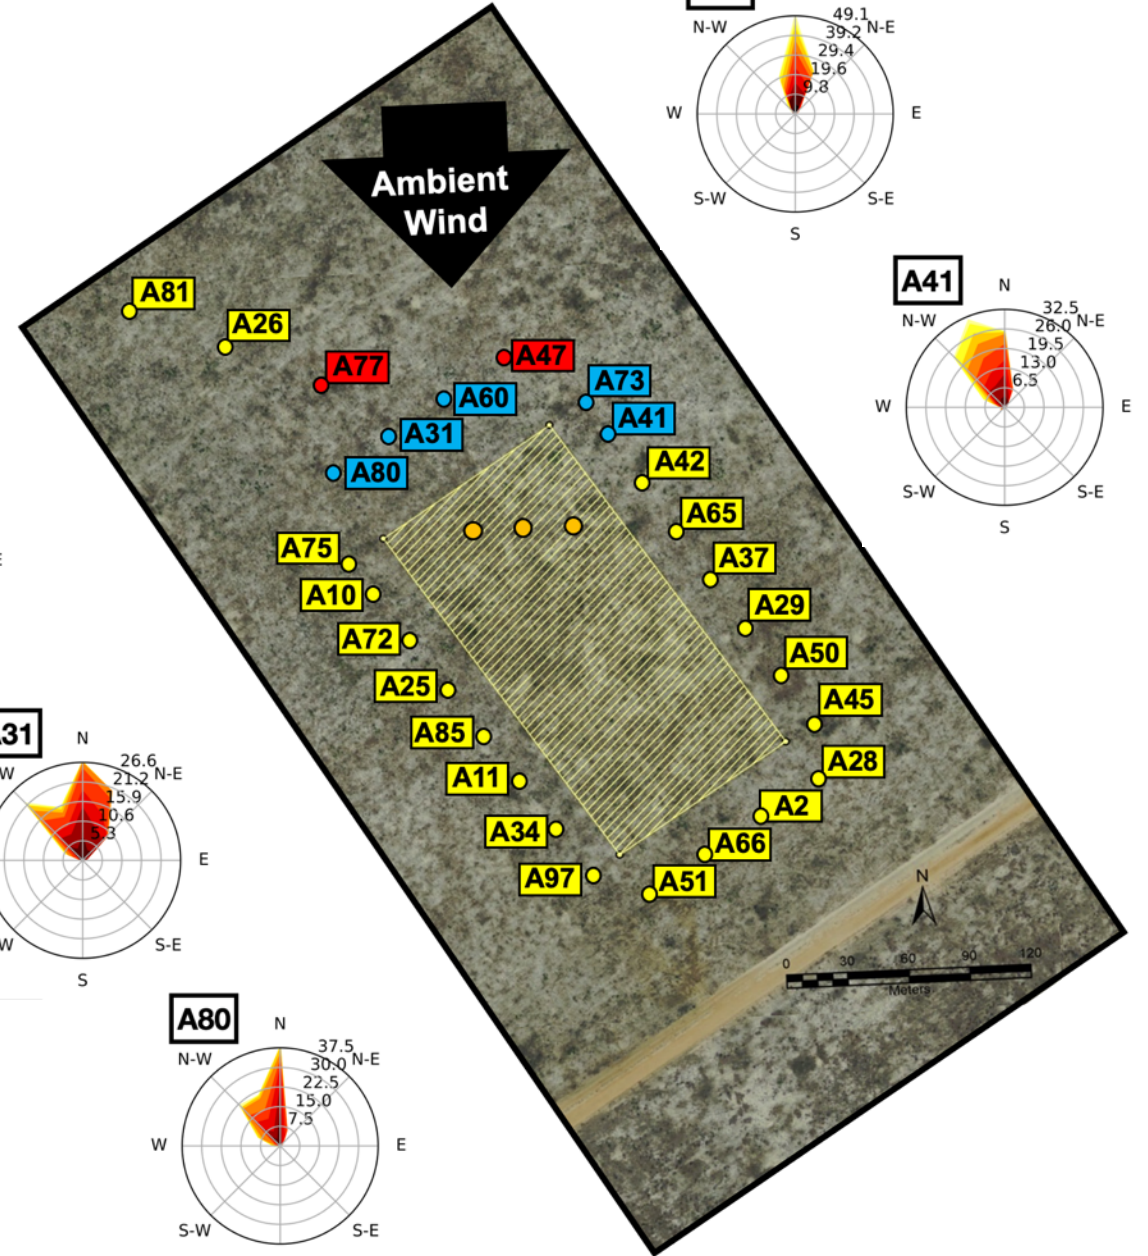

- Research tool that can be used for simplified simulations of certain aspects of fire behavior, or portions of real wildfires
- Has been used to inform prescribed fire planning
- Internal application: evaluate fire risk to LANL infrastructure

Movie removed for RASSTI

Are fires chaotic systems?

FIRETEC simulations of the RxCADRE fire experiment, using data from adjacent anemometers, show strong sensitivity of fire to perturbations in the turbulent wind field

Are fires chaotic systems?

FIRETEC simulations of the RxCADRE fire experiment, using data from adjacent anemometers, show strong sensitivity of fire to perturbations in the turbulent wind field

Study Design

1. Sensitivity to perturbations in atmospheric initial conditions

Fuels: homogenous grass

Winds: log profile: 2.5 m/s at 10 m

Vary:

- location of ignition within turbulent wind field
- fuel moisture

2. Sensitivity to perturbations in initial conditions of fuels

heterogenous Ponderosa Pine stands

log profile: 6.5 m/s at 25 m

- level of aggregation of trees
- location of ignition in heterogeneous fuel beds
- timing of ignition in turbulent wind field

1. Spin up a large turbulent wind field

- Turbulent wind spin up on large (1200 m x 1200 m) domain
- 9 small (400 m x 400 m) domains nested within for fire runs

Movie:

- 2 m horizontal wind speed across large domain
- small domain boundaries and ignition lines added for reference

1. Spin up a large turbulent wind field

2. Ignite fires in each of the 9 small domains

- Winds in each small domain do not interact with winds in neighboring domains.
- Fire in one domain is independent of the others.

3. Examine fire outcomes: Area burned

- Final fire scars from the first 9 simulations highlight variability.
- Next, we run 9 more fires in the same domains, moving ignition forward in time by 60 seconds.
- Since fuels are homogenous, we consider location and timing of ignition as interchangeable.

3. Examine fire outcomes: Area burned

12 fire scars from the first 9 simulations highlight variability.

Next, we run 9 more fires in the same domains, moving ignition forward in time by 60 seconds.

Since fuels are homogenous, we consider location and timing of ignition as interchangeable.

3. Examine fire outcomes: Area burned

om the first 9
light variability.

s.

3. Examine fire outcomes: Area burned

3. Examine fire outcomes: Clustering and diverging behavior

3. Examine fire outcomes:

Impacts of wind at time of ignition

The smallest fire in the ensemble is associated with low mean winds in x direction at the inlet

The largest fire in the ensemble is associated with high mean winds in x direction at the inlet

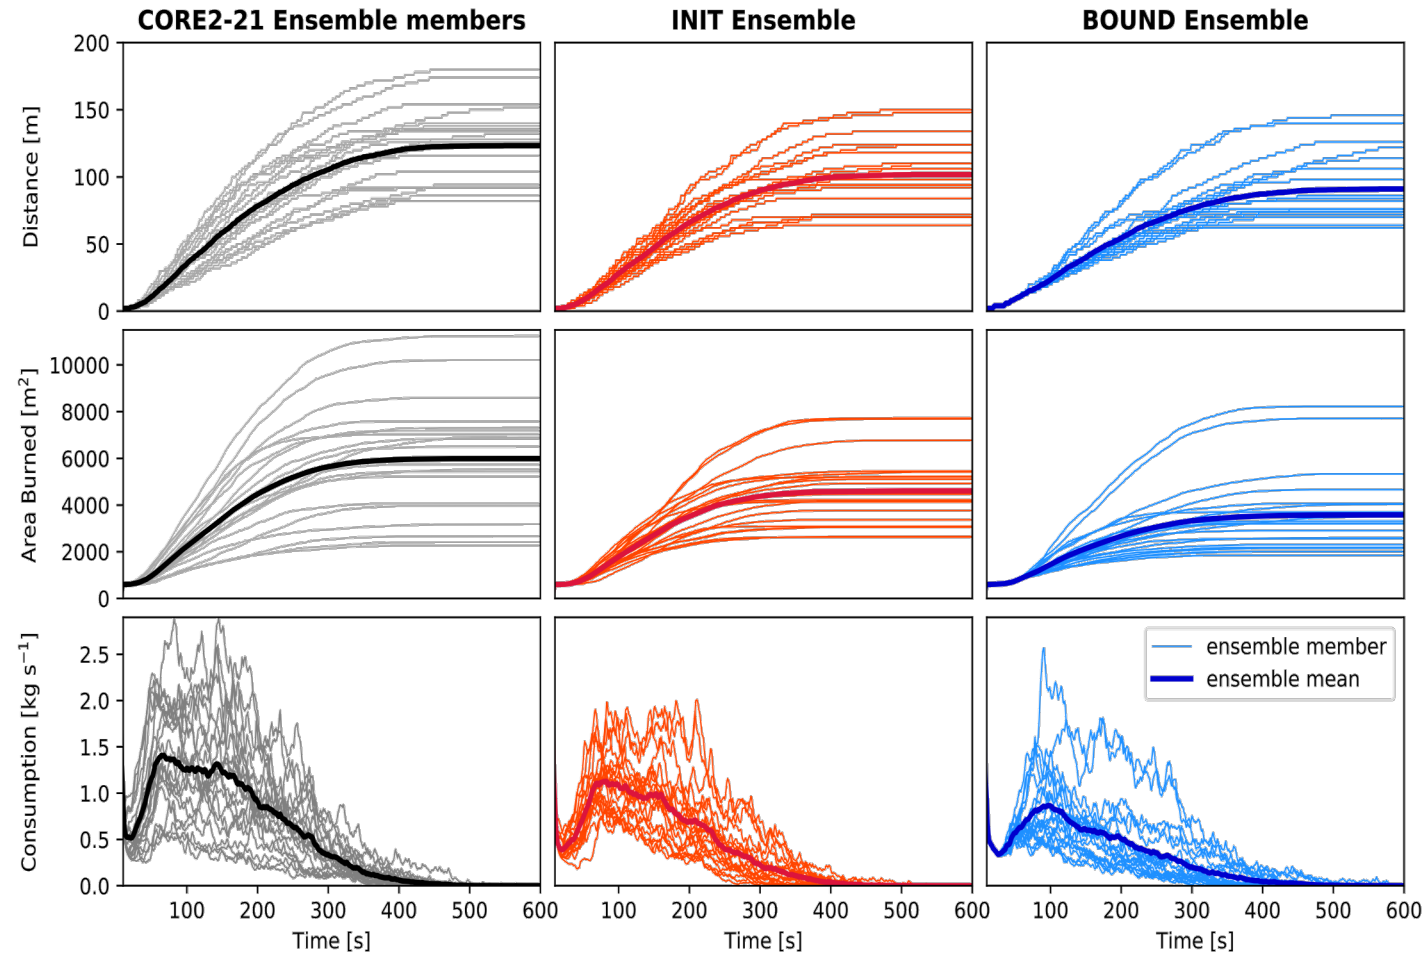

3. Examine fire outcomes:

Impacts of wind boundary vs initial conditions

3. Examine fire outcomes:

Impacts of wind boundary vs initial conditions

3. Examine fire outcomes:

Impacts of wind boundary vs initial conditions

Jonko et al. (2021) Sensitivity of grass fires burning in marginal conditions to small perturbations in the turbulent wind field. JGR Atmospheres (submitted).

Next, let's consider relationships between multiple parameters:

Add in sensitivity to perturbations in fuel initial conditions

Heterogeneous fuel beds – Ponderosa Pine

- **Tree measurements:**
- **To populate domains:**

Ponderosa Pine stand near Flagstaff, AZ

Simulate $1/f$ noise process using Inverse Discrete Fourier Transform

Levels of fuel aggregation

- Continuous surfaces with power spectral density $S(f) \sim 1/f^a$
- $a = 0 \rightarrow$ white noise, uncorrelated distribution of trees
- $a = 2 \rightarrow$ Brownian noise, very autocorrelated surface

Isolate impacts of turbulence in complex fuels:

Stagger ignitions in time

Consider effects of fuels and atmosphere:

Low fuel
aggregation

Consider effects of fuels and atmosphere:

Moderate fuel
aggregation

Consider effects of fuels and atmosphere:

High fuel
aggregation

Overview of some first results

	area burned:	surface fuels consumed:	canopy fuels consumed:
average	19432 m ² (12%)	3015 kg (6%)	7349 kg (4%)
coefficient of variation	0.43	0.44	0.54

average	22851 m ² (14%)	3600 kg (8%)	8046 kg (4%)
coefficient of variation	0.35	0.36	0.53

average	32968 m ² (21%)	5334 kg (11%)	10781 kg (6%)
coefficient of variation	0.40	0.41	0.85
